

Correctness of bbchallenge’s deciders

Tristan Stérin

Abstract

The Busy Beaver Challenge (or bbchallenge) aims at collaboratively solving the following conjecture: “ $BB(5) = 47,176,870$ ” [Aaronson, 2020]. This goal amounts to decide whether or not 88,664,064 Turing machines with 5-state halt or not – starting from all-0 tape. In order to decide the behavior of these machines we write *deciders*. A decider is a program that takes as input a Turing machine and outputs **true** if it is able to tell whether the machine halts or not. Each decider is specialised in recognising a particular type of behavior that can be decided.

In this document we are concerned with proving the correctness of these deciders programs. More context and information about this methodology are available at <https://bbchallenge.org>.

Table 1: Transition table of the current 5-state busy beaver champion: it halts after 47,176,870 steps.
<https://bbchallenge.org/1RB1LC1RC1RB1RD0LE1LA1LD---0LA&status=halt>

The set \mathbb{N} denotes $\{0, 1, 2 \dots\}$.

Turing machines. The Turing machines that are studied in the context of bbchallenge use a binary alphabet and a single bi-infinite tape. Machine transitions are either undefined (in which case the machine halts) or given by (a) a symbol to write (b) a direction to move (right or left) and (c) a state to go to. Table 1 gives the transition table of the current 5-state busy beaver champion. The machine halts after 47,176,870 steps (starting from all-0 tape) when it reads a 0 in state E, which is undefined.

A *configuration* of a Turing machine is defined by the 3-tuple: (i) state (ii) position of the head (iii) content of the memory tape. In the context of bbchallenge, *the initial configuration* of a machine is always (i) state is 0, i.e. the first state to appear in the machine’s description (ii) head’s position is 0 (iii) the initial tape is all-0 – i.e. each memory cell is containing 0. We write $c_1 \vdash_{\mathcal{M}} c_2$ if a configuration c_2 is obtained from c_1 in one computation step of machine \mathcal{M} . We omit \mathcal{M} if it is clear from context. We let $c_1 \vdash^s c_2$ denote a sequence of s computation steps, and let $c_1 \vdash^* c_2$ denote zero or more computation steps. We write $c_1 \vdash \perp$ if the machine halts after executing one computation step from configuration c_1 . In the context of bbchallenge, halting happens when an undefined machine transition is met i.e. no instruction is given for when the machine is in the state, tape position and tape corresponding to configuration c_1 .

Space-time diagram. We use space-time diagrams to give a visual representation of the behavior of a given machine. The space-time diagram of machine \mathcal{M} is an image where the i^{th} row of the image gives:

1. The content of the tape after i steps (black is 0 and white is 1).
2. The position of the head is colored to give state information using the following colours for 5-state machines: **A**, **B**, **C**, **D**, **E**.

2 Decider for “Cyclers”

Figure 1: Space-time diagrams of the 30 first steps of bbchallenge’s machines #279,081 (left) and #4,239,083 (right) which are both “Cyclers”: they eventually repeat the same configuration for ever. Access the machines at <https://bbchallenge/279081> and <https://bbchallenge/4239083>.

The goal of this decider is to recognise Turing machines that cycle through the same configurations for ever. Such machines never halt. The method is simple: remember every configuration seen by a machine and return **true** if one is visited twice. A time limit (maximum number of steps) is also given for running the test in practice: the algorithm recognises any machine whose cycle fits within this limit¹.

Example 1. Figure 1 gives the space-time diagrams of the 30 first iterations of two “Cyclers” machines: bbchallenge’s machines #279,081 (left) and #4,239,083 (right). Refer to <https://bbchallenge/279081> and <https://bbchallenge/4239083> for their transition tables. From these space-time diagrams we see that the machines eventually repeat the same configuration.

¹In practice, for machines with 5 states the decider was run with 1000 steps time limit.

2.1 Pseudocode

We assume that we are given a procedure **TuringMachineStep**(machine,configuration) which computes the next configuration of a Turing machine from the given configuration or **nil** if the machine halts at that step.

Algorithm 1 DECIDER-CYCLERS

```

1: struct Configuration {
2:   int state
3:   int headPosition
4:   int  $\vdash$  int tape
5: }
6: procedure DECIDER-CYCLERS(machine,timeLimit)
7:   Configuration currConfiguration = {state = 0, headPosition = 0, .tape = {0:0}}
8:   Set<Configuration> configurationsSeen = {}
9:   int currTime = 0
10:  while currTime < timeLimit do
11:    if currConfiguration in configurationsSeen then
12:      return true
13:    configurationsSeen.insert(currConfiguration)
14:    currConfiguration = TuringMachineStep(machine,currConfiguration)
15:    currTime += 1
16:    if currConfiguration == nil then
17:      return false //machine has halted
18:  return false

```

2.2 Correctness

Theorem 2. Let \mathcal{M} be a Turing machine and $t \in \mathbb{N}$ a time limit. Let c_0 be the initial configuration of the machine. There exists $i \in \mathbb{N}$ and $j \in \mathbb{N}$ such that $c_0 \vdash^i c_i \vdash^j c_i$ with $i + j \leq t$ if and only if $\text{DECIDER-CYCLERS}(\mathcal{M}, t)$ returns true.

Proof. This follows directly from the behavior of $\text{DECIDER-CYCLERS}(\mathcal{M}, t)$: all intermediate configurations below time t are recorded and the algorithm returns true if and only if one is visited twice. This mathematically translates to there exists $i \in \mathbb{N}$ and $j \in \mathbb{N}$ such that $c_0 \vdash^i c_i \vdash^j c_i$ with $i + j \leq t$, which is what we want. Index i corresponds to the first time that c_i is seen (l.13 in Algorithm 1) while index j corresponds to the second time that c_i is seen (l.11 in Algorithm 1). \square

Corollary 3. Let \mathcal{M} be a Turing machine and $t \in \mathbb{N}$ a time limit. If $\text{DECIDER-CYCLERS}(\mathcal{M}, t)$ returns true then the behavior of \mathcal{M} from all-0 tape has been decided: \mathcal{M} does not halt.

Proof. By Theorem 2, there exists $i \in \mathbb{N}$ and $j \in \mathbb{N}$ such that $c_0 \vdash^i c_i \vdash^j c_i$ with $i + j \leq t$. It follows that for all $k \in \mathbb{N}$, $c_0 \vdash^{i+kj} c_i$. The machine never halts as it will visit c_i infinitely often. \square

3 Decider for “Translated cyclers”

Figure 2: Example “Translated cycler”: 45-step space-time diagram of bbchallenge’s machine #44,394,115. See <https://bbchallenge.org/44394115>. The same bounded pattern is being translated to the right for ever. The text annotations illustrate the main idea recognising “Translated Cyclers”: find two configurations that break a record (i.e. visit a memory cell that was never visited before) in the same state (here state **D**) such that the content of the memory tape at distance L from the record positions is the same in both record configurations. Distance L is defined as being the maximum distance to record position 1 that was visited between the configuration of record 1 and record 2.

The goal of this decider is to recognise Turing machines that translate a bounded pattern for ever. We call such machines “Translated cyclers”. They are close to “Cyclers” (Section 2) in the sense that they are only repeating a pattern but there is added complexity as they are able to translate the pattern in space at the same time, hence the decider for Cyclers cannot directly apply here.

The main idea for this decider is illustrated in Figure 2 which gives the space-time diagram of a “Translated cycler”: bbchallenge’s machine #44,394,115 (c.f. <https://bbchallenge.org/44394115>). The idea is to find two configurations that break a record (i.e. visit a memory cell that was never visited before) in the same state (here state **D**) such that the content of the memory tape at distance L from the record positions is the same in both record configurations. Distance L is defined as being the maximum distance to record position 1 that was visited between the configuration of record 1 and record 2. In those conditions, we can prove that the machine will never halt.

The translated cycler of Figure 2 features a relatively simple repeating pattern and transient pattern (pattern occurring before the repeating patterns starts). These can get significantly more complex, bbchallenge’s machine #59,090,563 is an example see Figure 3 and <https://bbchallenge.org/59090563>. The method for detecting the behavior is the same but more resources are needed.

Figure 3: More complex “Translated cycler”: 10,000-step space-time diagram (no state colours) of bbchallenge’s machine #59,090,563. See <https://bbchallenge.org/59090563>.
